Coastal Remote Sensing Observations

Remote sensing radiance spectra are composites of radiance (reflectance) from:

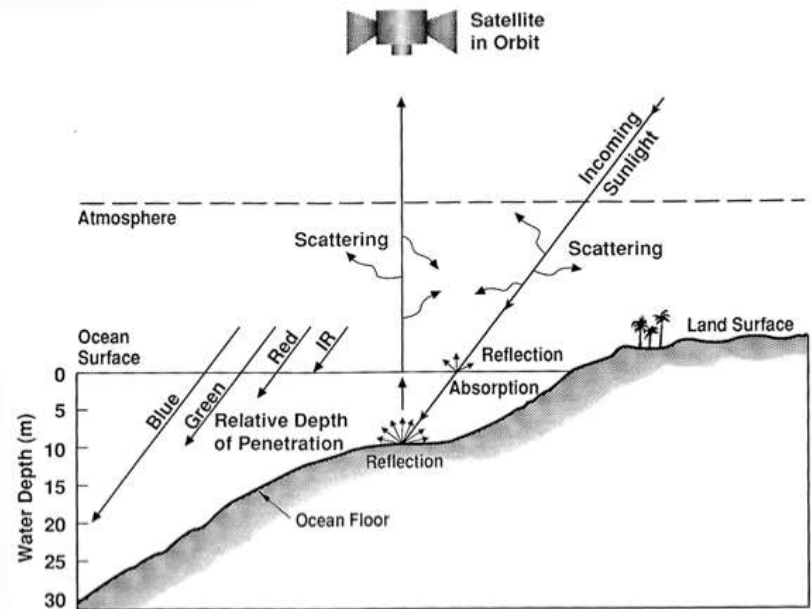

1. the atmosphere (gas molecules, particulates, aerosols, water vapor);
2. the sea surface;
3. the water column (water molecules, phytoplankton, colored dissolved organic matter); and
4. the bottom

~80% of the signal is scattered or absorbed by the atmosphere

Challenges of Coastal Remote Sensing

- Water is a dark target with high sensor signal (SNR) requirements
- Two factors that limit the accuracy of retrievals for coastal ocean color:
 1. accurate atmospheric correction (aerosol and trace gas plumes from continental sources)
 2. accurate retrieval of water column and benthic ecosystem reflectance

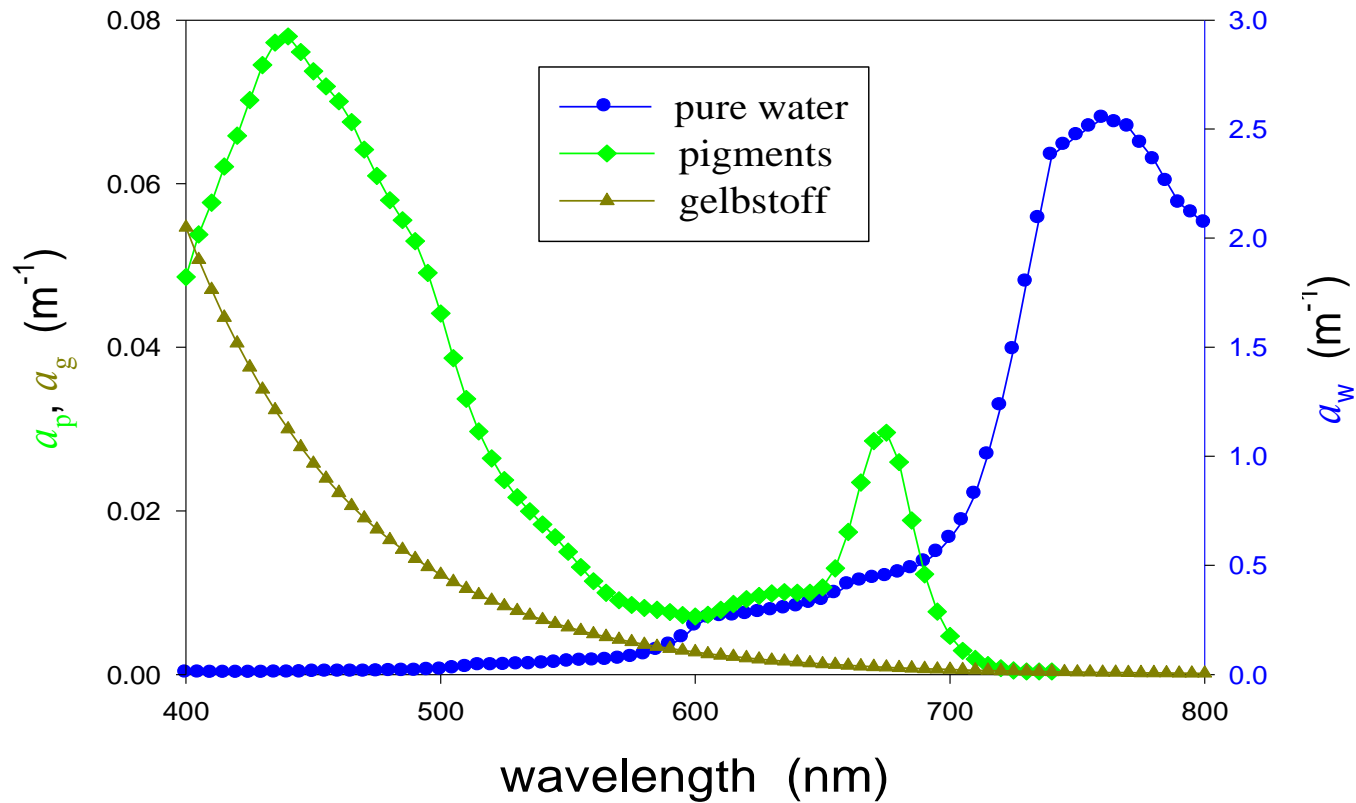

- Need for sensors with high dynamic range for benthic habitats under variable bathymetry and with adequate spatial resolution

What does the color of the water tell us?

Absorption spectra for water, CDOM, and phytoplankton

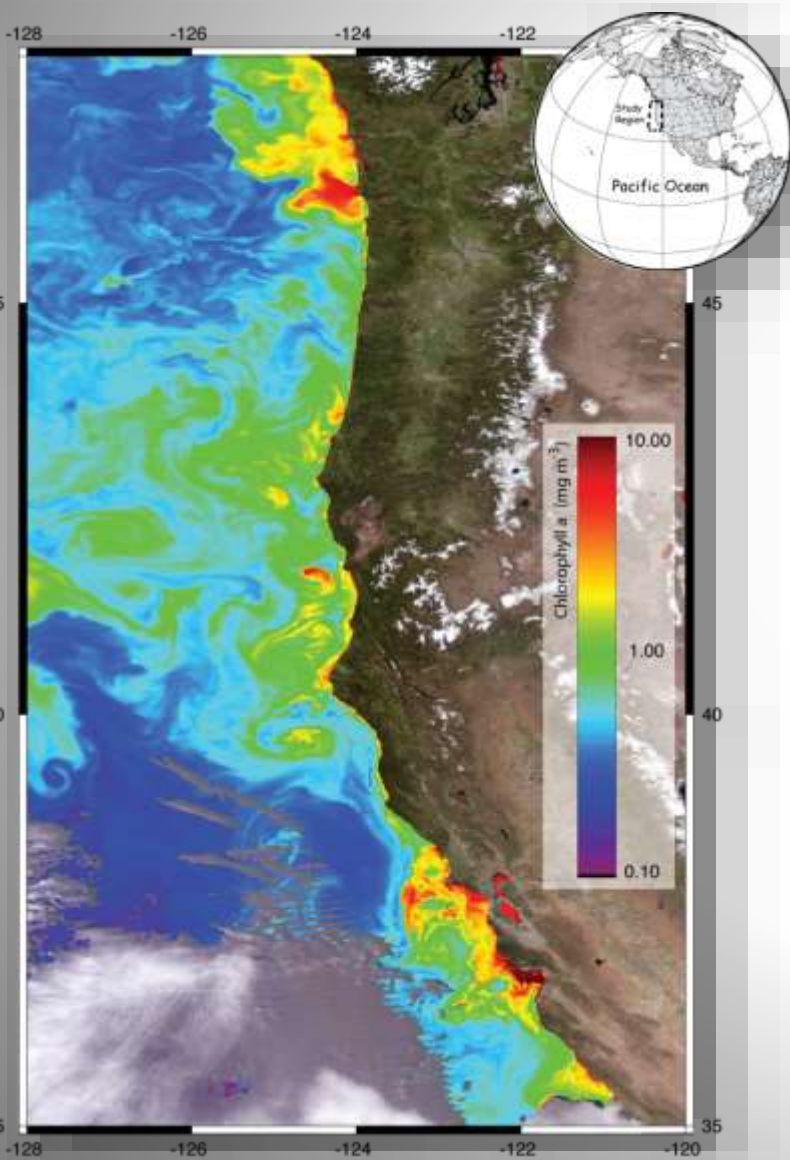

absorption spectra

Optically-shallow vs. optically-deep waters

Case Study: Monterey Bay, California

Ship and Airborne-based Measurements: Monterey Bay

- Underway T, S, Fluorescence
- At each station (2-3 stations per day):
 - Size fractionated chlorophyll, phytoplankton species ID
 - CDOM, absorption spectra, nutrients
 - Sun photometer spectra
 - HyperPro cast, C-OPS cast
 - Water-leaving radiance, profile data
 - Backscatter/ac-s casts
 - ASD surface reflectance

NASA COAST October 28, 2011

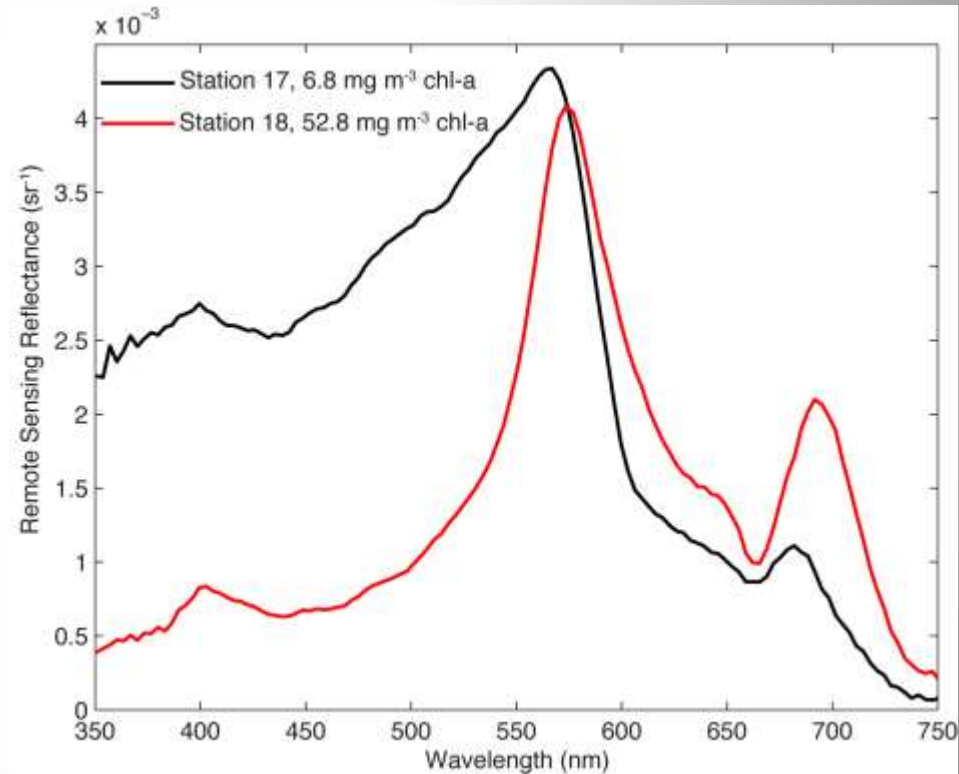

Imaging Spectrometer Imagery, Site Location, Sea-truth Measurements

Not Red Tide = Station 17, Flightline 29

Red Tide = Station 18, Flightline 28

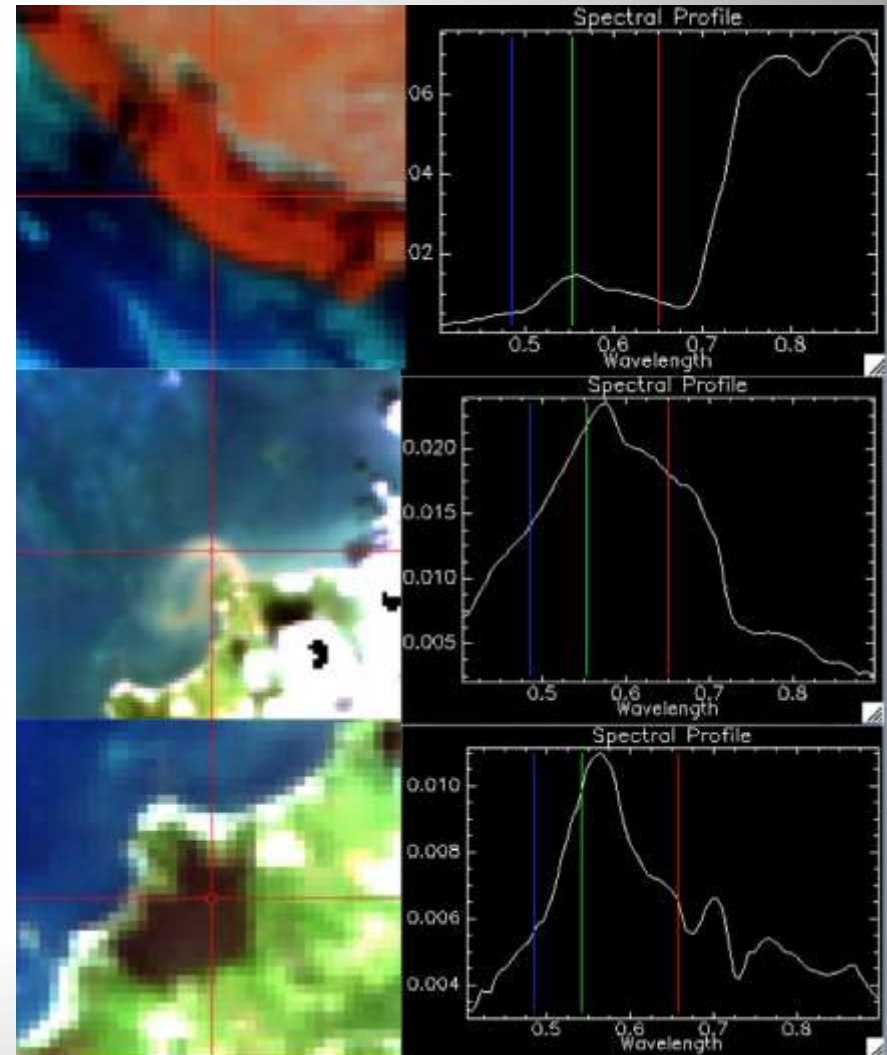

Ship-based HyperPro II measurements

Airborne measurements of water-leaving radiance (imaging spectrometer) were collected at the same time as AOD and CWV from a sun photometer. Ship-based measurements (red tide, not red tide) collected +/- 30 min of airborne data collection.

Requirements for Water Quality Remote Sensing

- Measurements over spatial extents from < 10 m to 100s of meters. However, most satellite ocean color data have a spatial resolution of about 1 km
- Coastal ocean phenomena are measured at different temporal scales
 - Timing is important for capturing transient phenomena (e.g. hours to days) – hence the need for high resolution geostationary data
- Optically-complex coastal waters require hyperspectral data for spectrally separating the signals from optically-competing water column parameters

ISS HICO Data

Case Study: Southwestern Puerto Rico

December 12, 2007

Sampling Stations – SW Puerto Rico

Ship-based Measurements: SW Puerto Rico

Biogeochemical Properties

Surface water samples are used for measuring CDOM, Total Suspended Matter, and Chlorophyll.

IOPs: a, c, b_b

Profiling sensor package that includes a CTD, a WetStar fluorometer, an ac-9 for absorption and attenuation, and a HydroScat-6 for backscattering.

AOP: Lu, Ed, Rrs

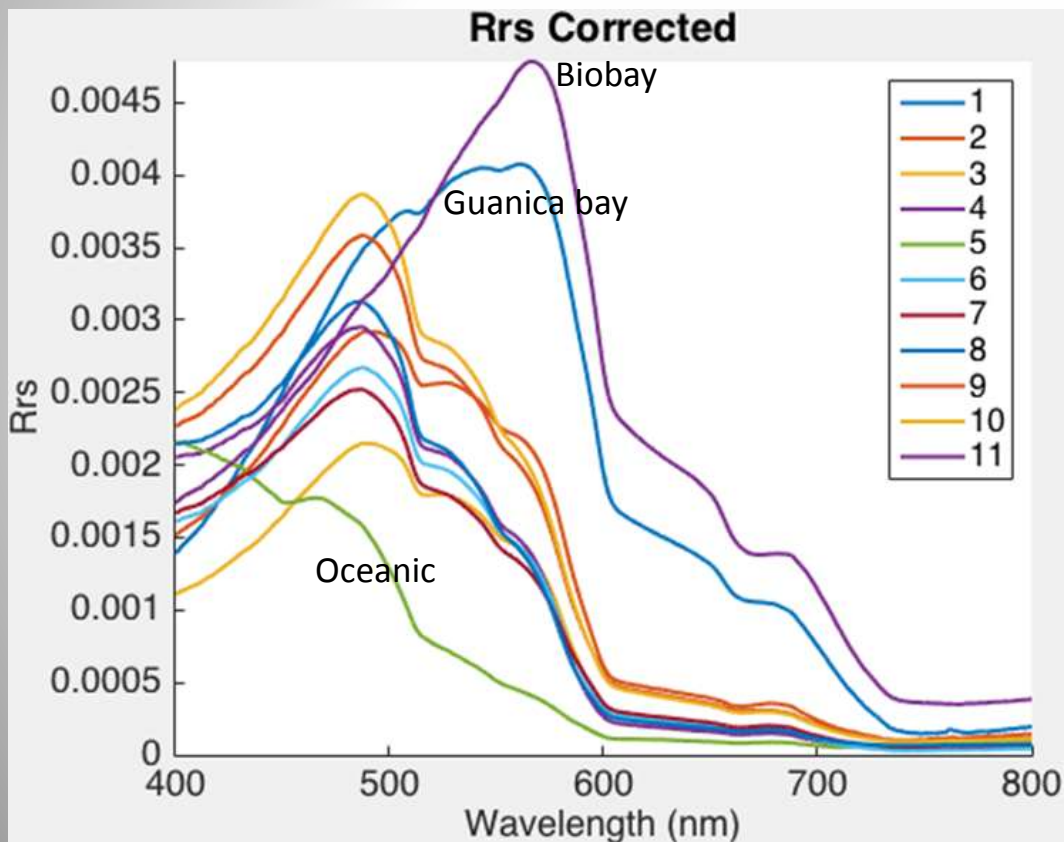

GER-1500 spectroradiometer measures Lu, Ls, and Ed. This is used to calculate Rrs.

Satlantic HyperPro Profiling Spectroradiometer.

Results- Field Sampling

GER1500 surface remote sensing reflectance

Chlorophyll a

Kd (490) Values (Turbidity)

Conclusions

- Coastal ocean color algorithms are sensitive to errors in atmospheric correction models, the presence of nearby clouds, sensor calibration, low sensor signal, and sunglint correction.
- Spatial resolution of existing satellite ocean color sensors is usually too coarse for coastal zone studies.
- Sampling frequency of existing satellite sensors can be inadequate for capturing transient phenomena such as red tides and algal blooms.
- Cloud cover limits the amount of usable imagery.
- Optically-complex coastal waters require hyperspectral data for separating the signals from water column parameters.
